20. ABSTRACT (Continue on reverse side if necessary and identify by block number) The purpose of this data report was to document information gathered during the past five years on a field study on slow infiltration land treatment of wastewater. Emphasis was focused on presenting actual data as well as detailed descriptions of the methods used. Very little discussion is included. The report is divided into two main sections. Section I deals with physical properties of the two soils used and the changes in soil chemical characteristics during the five years of investigation. The physical properties of the soil are those most important in controlling the rate of water movement in soils.

CONT'

such as saturated and unsaturated soil hydraulic conductivity, particle size distribution, bulk density, void ratio, available water and specific gravity. The chemical characteristics of the soil that are of potential importance in assessing the short and long-term effects of wastewater application on land include: free iron oxides, organic carbon, organic nitrogen, pH, conductivity, cation exchange capacity, exchangeable cations, total and extractable phosphorus, and total and extractable heavy metals. Section II summarizes climatic conditions at the CRREL site in Hanover, New Hampshire, and the changes that occurred during the period 1974 to 1978. Climatic parameters include temperature, precipitation, wind speed, and soil temperature at depth. It is hoped that the data could be used by other workers for model validation; however, proper citation of the source of the data must be included. Further information may be obtained by writing to the authors.

## PREFACE

This report was prepared by Dr. I.K. Iskandar, Research Chemist, S.T. Quarry, Physical Science Technician, R.E. Bates, Meteorologist, Snow and Ice Branch, Research Division; and by J. Ingersoll, Civil Engineering Technician, Geotechnical Research Branch, Experimental Engineering Division, U.S. Army Cold Regions Research and Engineering Laboratory, Hanover, N.H.

This study was funded under

CWIS No. 31280, Evaluation of Existing Facilities for Wastewater Land Treatment;

CWIS No. 31297, Optimization of Management Techniques for Wastewater Renovation;

CWIS No. 31314, Nitrogen Transformation in Land Treatment Systems; and

CWIS No. 31480, Long-Term Effects of Heavy Metals in Land Treatment.

The efforts of several investigators in collection of the data during the initial phases of the program are greatly appreciated. The authors would like to thank Dr. R.P. Murrmann, S. Reed, Dr. H.L. McKim, W. Richard and T. Buzzell for initial design of the CRREL prototype test cells; D.C. Leggett, T.F. Jenkins and P. Schumacher for analysis of water samples; T. Palazzo for forage grass management and data on plant yield and uptake of nutrients; R. Sletten, J. Martel, D. Keller and J. Bayer for supervision of the pretreatment facilities; and F. Page for developing computer programs for data storage and retrotime. The authors would also like to thank the U.S. Army Meteorological Team, Hanover, N.H., for furnishing the instrumentation and collection of the meteorological data, and the computer staff at CRREL for data reduction and storage.

## INTRODUCTION

Treatment and disposal of wastewater by application on land has attracted many researchers in recent years. This is not a new concept because systems were designed and built as early as the sixteenth century in Europe (Iskandar 1978) and probably much earlier than that in China and Greece. The present interest, however, is in the treatment of wastewater on a cost effective basis and in the protection of our environment from pollution. Mathematical models may be used to optimize the utilization of a land treatment system. However, the available models lack validation. There is also a lack of information in the literature on the long-term effects of wastewater application on land for the purpose of treatment.

The purpose of this report is to summarize available data on a rather long-term experiment conducted to obtain data both for model validation and for addressing potential long-term effects of wastewater application on land. Although several mathematical models are being checked with these data at CRREL at the present time, the authors feel that the data obtained during the past five years are invaluable and that other researchers and modelers should have the opportunity to utilize this information.

In this report, the analytical methods are described in detail and little discussion is presented. It should be mentioned that reported data for the initial phases of the study (1973 and 1974) are from analyses performed at a commercial laboratory, while later analyses were done at CRREL. Despite efforts to employ the same analytical methods, some inconsistencies in the concentrations of P or trace metals could be due to the differences between the two laboratories.

This report is written in two sections: Section I summarizes the changes in soil characteristics during the study period. For more information on the plant yield and analysis of applied and percolated effluent during the study period, the reader should consult Jenkins et al (1978), and Iskandar et al (1976). Section II summarizes the climatic data near the land treatment test facilities at CRREL and is a continuation of the report by Bilello and Bates (1978). The previous report included meteorological data recorded during the period October 1972 through March 1974. Section II presents meteorological data for the period April 1974-May 1978.

Climatic restraints on the renovation of wastewater have been a problem for many geographical areas, especially in cold and humid regions and in areas where unsuitable soil conditions for land treatment exist. The meteorological variables which were measured continuously at the CRREL climatic station include; precipitation, air temperature, relative humidity, snow depth, wind speed and direction, solar radiation, evaporation and soil temperature.

The CRREL Outdoor Land Treatment Research Facility was designed to investigate the slow infiltration mode of land treatment and consists of the following major components as shown in Figure 1: a) six large-scale outdoor test cells containing two different soil types, Windsor sandy loam

and Charlton silt loam; b) conventional pre-application treatment processes to produce both primary and secondary treated effluents; c) the capability for routine on-line disinfection with ozone prior to land application; d) the capacity to add desired materials to the raw wastewater to simulate industrial contributions; and e) a climatology station.

Tables 1 and 2 summarize the wastewater loading rates for the test cells and the periods of application, respectively, during the period 1973 to 1978.

## SECTION I. SELECTED SOIL PHYSICAL and CHEMICAL PROPERTIES

The soils used in the test cells were Windsor sandy loam, and Charlton silt loam, representing two textural classes; however, both are classified as Entic Haplorthode according to the 7th approximation.

### Hydraulic characteristics of Windsor and Charlton Soils Before Wastewater Applications.

Several hydraulic characteristics of soils must be known in order to determine the maximum application rate of liquid waste. Of these parameters, the saturated and unsaturated hydraulic conductivity and diffusivity are the most important. The first parameter, also known as the permeability of the soil, determines the rate at which water passes through the soil when it is saturated with water. Table 3 summarizes the permeability data for both Windsor and Charlton soils. These data were obtained by using a Lucite cylinder of approximately 10-cm length and 5-cm diameter. A constant head was used and at least two densities of each soil and two runs at each density were tested. Data in Table 3 demonstrate the higher permeability of Windsor soil compared to Charlton soil. It is therefore expected that wastewater could be applied to the Windsor soil at a higher rate. Also, the residence time of water is much shorter in the Windsor soil. The constant head permeability was calculated from (1)

$$\text{Constant head permeability } K_{20} = \frac{QLR_T}{hAt} \quad (1)$$

Where

$Q$  = quantity of water flow,  $\text{cm}^3$

$h$  = hydraulic head,  $\text{cm}$

$t$  = elapsed time,  $\text{sec}$

$L$  = length of travel,  $\text{cm}$

$A$  = Cross section area,  $\text{cm}^2$

$R_T$  = temperature correction for water viscosity

The hydraulic conductivity unsaturated, on the other hand, determines the rate of water movement when the soil pores are partially saturated with water and partially with air. This is a rather difficult measurement. Several investigators (Green and Corey 1971) estimated the unsaturated soil hydraulic conductivity from a moisture retention - water content function and the permeability data of the soil. The estimated values compared well with the measured values for many soils.

The moisture retention curve was obtained by plotting the volumetric water content as a function of tension ( $\text{cm H}_2\text{O}$ ). Figures 2 to 7 show the moisture retention curves for Windsor and Charlton soils.

Moisture retention characteristics for the Charlton soils were

determined using Tempe cells. This procedure provides a desorption curve only. The curves relating to the Windsor soils were determined using a volumetric plate extractor to obtain both the adsorption and desorption curves. Assuming that the tension is zero at the saturated hydraulic conductivity (permeability) and using a model developed initially by Green and Corey (1971), the unsaturated hydraulic conductivity of the soil can be estimated.

#### Particle size analysis

The particle size analyses of the soils were performed by sieving for the coarse particles and by sieving with a hydrometer method for the fine particles. All analyses were done by the Soils Laboratory at CRREL. Figures 8 and 9 illustrate the results obtained for the Windsor and Charlton soils. In Windsor soil the clay content is <1%, the silt (50-2  $\mu\text{m}$ ) ranges from 8 to 12%, and the sand (> 50  $\mu\text{m}$ ) is about 90%. The Charlton soil has a clay content <5% throughout the profile with the silt and sand percentages being 35  $\pm$  5% and 60  $\pm$  5% respectively.

#### Soil Bulk Density

The bulk density was calculated by dividing the oven-dry soil weight in grams by the volume occupied. Table 31 contains data on soil bulk density expressed in grams/cm<sup>3</sup>. The bulk density of the different horizons ranged from 1.1 (horizon A Charlton) to 1.8 (horizon C Windsor). The low bulk density of horizon A Charlton is probably due to the higher content of organic matter of low bulk density.

#### Other Soil Physical Parameters:

There are many other soil physical parameters that could affect to variable degrees the water movement characteristics of a land treatment site. However, only the most important factors will be defined in this report.

#### Soil Chemical Analysis

Soil core samples were taken in April of each year since 1973 (before wastewater application). Each core was divided into 15-cm increments. Samples were composited after collection and were air-dried before analysis or shipping to the U.S. Testing Laboratory, Memphis, Tennessee, for analysis. Analyses of the samples collected in 1973 and 1974 were conducted at the U.S. Testing Laboratory, while the others were done at CRREL. After drying, the soils were passed through a 2-mm stainless steel sieve, and the less than 2-mm-diameter fraction was determined. This fraction was stored in plastic-lined paper bags until analyzed. The following methods were used.

### Soil pH

The method used to determine pH was similar to that reported in Methods for Soil Analysis (Black 1965, section 60-3.4). Twenty ml of distilled water were added to 20 g of soil. The suspension obtained was mixed with a mechanical stirrer for 1 hour. The pH was read directly using a standard glass/calomel electrode pair while the mixture was agitated. Results were reported to the nearest 0.1 pH unit.

### Soluble salts (conductivity)

The solution from the sample prepared for the pH determination was subsequently filtered through a Buchner funnel (Whatman no. 1 filter paper). The overall procedure was similar to that reported in Methods for Soil Analysis (Black 1965, sections 62-1.3.2.2 and 62-2). Electrical conductivity was determined using a standard Wheatstone bridge with a dip-type conductivity cell (cell constant=1.0). Results were reported to the nearest 0.01 mmhos/cm.

### Cation exchange capacity (CEC)

The method used to determine CEC is similar to that reported in Methods for Soil Analysis (Black 1965, sections 57-2.1 and 57-2.3). One hundred ml of 1 N  $\text{NH}_4\text{OAc}$ , pH 7 were added to 20 g of soil. The mixture was shaken for 1 hour and allowed to settle overnight. It was then filtered through a Buchner funnel fitted to a suction flask. The sample was leached incrementally with additional  $\text{NH}_4\text{OAc}$  solution to obtain a total volume of 200-225 ml of filtrate. The filtrate was transferred to a 250-ml volumetric flask and made up to that volume with  $\text{NH}_4\text{OAc}$ . This solution was set aside for determination of individual exchangeable cations, as described in the next section.

The soil in the Buchner funnel was then leached incrementally with 200-250 ml of isopropyl alcohol to remove excess  $\text{NH}_4\text{OAc}$ . Distilled water was used to transfer the soil to a Kjeldahl flask (800 ml); boiling stones, 450-500 ml of distilled water, and 25 ml of 1 N NaOH were then added to the flask. The sample was then distilled into 50 ml of 4% boric acid. A total of about 200 ml of distillate was collected. The final distillate was titrated with 0.1 N HCl using an indicator solution. The milliequivalents of  $\text{NH}_3$  collected are equivalent to the exchange capacity when expressed in milliequivalents per 100 g of soil.

### Exchangeable cations

The  $\text{NH}_4\text{OAC}$  extract from the CEC determination was analyzed for individual exchangeable cations ( $\text{Na}^+$ ,  $\text{K}^+$ ,  $\text{Ca}^{2+}$ ,  $\text{Mg}^{2+}$ ) with a Perkin-Elmer Model 403 atomic absorption spectrophotometer using an air/acetylene flame. Instrument settings were established using procedures recommended by the manufacturer (Perkin Elmer 1971). Results were expressed as parts per million of cations on a weight basis. This procedure for extraction of exchangeable cations is similar to that recommended by

Jackson (1958, section 5-11).

#### Organic carbon

Organic carbon was determined by a Walkely-Black method similar to that outlined in Methods for Soil Analysis (Black 1965, section 90-3). Either 1.0 g or 0.5 g of soil, depending on the level of organic matter, was mixed with 10 ml of 1 N  $K_2Cr_2O_7$  in a 250-ml Erlenmyer flask. Twenty ml of concentrated  $H_2SO_4$  were added to the flask, the mixture was swirled for 1 min, and then allowed to cool for about 30 min. Water (150 ml) and several drops of o-phenanthroline indicator were added, and the resulting mixture was allowed to recool. The suspension was titrated with 0.5 N  $Fe(NH_4)_2(SO_4)_2$ . The chromate was standardized by repeating the procedure without soil. The percentage of organic carbon was calculated using the following equation (Black 1965):

$$\% \text{ Organic C} = \frac{\text{meq } K_2Cr_2O_7 - \text{meq } Fe(NH_4)_2(SO_4)_2}{\text{g dry soil}} \times 0.3.$$

No correction factor (normally  $\times 1.33$ ) was applied in making the calculation.

#### Organic-Nitrogen

Organic nitrogen was determined using a Kjeldahl method similar to that outlined in Methods for Soil Analysis (Black 1965, section 83-3). It was assumed that the exchangeable ammonium contribution was insignificant so that the result represented organic nitrogen. Ten g of soil was mixed with 20 ml of water in an 800-ml Kjeldahl flask, and then 0.1 g  $HgO$ (red) and 30 ml of concentrated  $H_2SO_4$  were added. The mixture was digested, according to the standard procedure, for 5 hours. The sample was cooled, 500 ml distilled water was added, and the sample was then re-cooled. To the same flask, 25 ml of 16%  $Na_2S_2O_4$  solution and several granules of mossy zinc were added and 50 ml of distillate was collected in 50 ml of 4% boric acid. The distillate was titrated with 0.1 N HCl using the standard indicator solution. The results were expressed in terms of percentage of organic-N on a dry weight basis.

#### Free iron oxides

The procedure followed was that given in Methods of Soil Analysis (Black 1965, section 65-4). Five g of air-dried soil, 5 g of  $Na_2S_2O_4$  and 100 ml of water were placed in a flask, which was then immediately shaken for 16 hours. The suspension was transferred to a 250-ml beaker, the pH was adjusted to 3.5 to 4.0 with 1 N HCl, and the suspension was stirred several times over one hour period. The suspension was transferred to a 250-ml volumetric flask, diluted to that volume with water, and mixed. Five ml of clear filtered extract was transferred to a 250-ml

beaker using a mechanical source of suction to fill a 50-ml pipette. The solution was diluted to about 100 ml, 15 ml of  $H_2O_2$  was added, and the contents were boiled again for 5 to 10 min.

A small excess of 7 N  $NH_4OH$  was added and the solution was boiled 15 to 20 min. The  $Fe(OH)_3$  precipitate was dissolved by adding 15 ml of 6 N HCl through the lip of the covered beaker. The solution was heated to 90°C, and the Fe reduced by adding  $SnCl_2$  reagent dropwise and stirring the solution until the yellow color disappeared. An excess of 4 drops of  $SnCl_2$  was added, the solution was cooled to room temperature, and 15 ml of saturated  $HgCl_2$  was added rapidly from a volumetric cylinder.

The solution was diluted to about 125 ml, and then 5 ml of 85%  $H_3PO_4$  and 10 drops of 0.16% barium diphenylamine sulfonate were added. The solution was titrated with standardized 0.1 N  $K_2Cr_2O_7$  to a violet-blue endpoint. The free Fe oxides as percentage of  $Fe_2O_3$  in the soil were calculated as follows:

$$\text{Free Fe oxides} = (\text{ml of } K_2Cr_2O_7)(\text{Normality of } K_2Cr_2O_7)(7.92).$$

#### Organic phosphorus

The method used for determination of organic phosphorus was adapted from those recommended in Methods of Analysis (Black 1965, section 73-3) and Sanders (1955). Two g of soil were ignited in a silica crucible for one hour at 550°C. The ignited sample and a duplicate 2 g unignited sample was then extracted by shaking for 2 hours with 100 ml of 0.2 N  $H_2SO_4$  in a shaker. Inorganic phosphorus in the extracts was determined using a standard molybdate method (Orr 1971). An aliquot of a sample 3-10 ml in volume, depending on concentration, was mixed with 2 ml of ammonium molybdate-HCl reagent and 2 ml of Elon reagent. The solution was diluted to a 25-ml volume and allowed 15 min for color development. Color intensities of the samples, blanks, and standards carried through the extraction procedure were determined using a colorimeter. The increased phosphorus resulting from ignition was taken to represent organic phosphorus. Results were expressed as parts per million on a weight basis.

#### Total phosphorus

Total phosphorus was determined using two methods. The first method was an acid-digestion technique. Later, in determining organic phosphorus, it was found that total phosphorus obtained by ignition was different (frequently higher) than that obtained by digestion. Consequently, both values were reported when available.

The digestion method employed was that in Methods of Soil Analysis (Black 1965, section 73-2). Two g of soil were treated with 30 ml of 60%  $HCLO_4$  in a 250-ml volumetric flask. The mixture, after digestion on a hot plate until white  $HCLO_4$  fumes appeared (3-4 hours), was cooled and made up to a 250-ml volume with distilled water. The solution was then filtered before analysis for total phosphorus using the molybdate method (Orr 1971) employed above for analysis of organic phosphorus. Results

were expressed as parts per million of phosphorus on a weight basis.

The value obtained for ignited samples during the procedure for determination of organic phosphorus was taken to represent total phosphorus.

#### Extractable phosphorus

Extractable phosphorus was determined using the Bray technique for estimating plant available phosphorus. The extraction procedure used was similar to that in Methods of Soil Analysis (Black 1965, section 73-4.1). One g of soil was shaken for 5 min with 10 ml of 0.03 N  $\text{NH}_4\text{F}$  - 0.025 N HCl solution. The suspension was filtered to obtain the clear extract. Two ml of the extract was added to 4 ml of extracting solution. The phosphorus was determined colorimetrically using the procedure (Black 1965) described for organic phosphorus, except that 0.5 ml each of molybdate and Elon reagents were added directly to the 6 ml of prepared sample. Results were expressed as parts per million phosphorus on a weight basis.

#### Soluble phosphorus

A procedure similar to that described in Methods for Soil Analysis (Black 1965, section 73-4.3) was employed to extract soluble phosphorus. Twenty ml of distilled water was added to 10 g of soil in a sample bottle. The mixture was shaken for 24 hours and a clear extract was obtained by filtering. Molybdate and Elon reagents (0.5 ml each) were added directly to 6 ml of soil solution. The colorimetric procedure (Orr 1971) was similar to that used for organic phosphorus. Results were expressed as parts per million on a dry weight basis with respect to soil. Soluble phosphorus with respect to solution concentration is equal to one-half the reported value, since 10 g of soil was equilibrated with 20 g of water.

#### Total heavy metals

For the analysis of cadmium, copper, zinc, nickel, chromium, lead, two g of soil were digested with 20 ml of concentrated  $\text{HNO}_3$  in a 100-ml volumetric flask on a hot plate for 30 min. The mixture was cooled, after which 10 ml of concentrated  $\text{HClO}_4$  and 5 ml of concentrated  $\text{H}_2\text{SO}_4$  were added. The sample was redigested for 5 hours or until the volume of remaining acid was reduced to about 5 ml. The volume was then increased to 100 ml with distilled water and the sample filtered. The concentrations of heavy metals were determined directly on the extract using a Perkin-Elmer 403 atomic adsorption spectrometer. An air/acetylene flame was used when the concentration of a given element was sufficiently high. For low concentrations, a Perkin-Elmer (1973) HGA 2100 graphite furnace was employed. Instrument settings were established using procedures recommended by Perkin Elmer (1971, 1973). Results were reported on a parts per million or billion by weight basis.

Mercury was determined by digesting 1 g of soil with 5 ml of concentrated  $\text{HNO}_3$  in a 300-ml BOD bottle, heating on a hot plate for 30 min at 60°C after the initial oxidation of organic matter occurred. A second state of digestion was achieved by adding 15 ml of aqua regia with further heating for 60 min at the same temperature. The above digestion procedure has been reported in detail by Hamm (1973). Mercury in the digestate was determined with a Coleman Mercury Analyzer MAS-50 using the manufacturer's (Perkin Elmer 1972) suggested procedure. The digested sample was diluted to 100 ml with distilled water. Five ml of 5%  $\text{KMnO}_4$  were then added and the solution was mixed. Other oxidizing reagents were added next in sequence: 5 ml of 5.6 N  $\text{HNO}_3$  (swirl and wait 15 s); 5 ml 18 N  $\text{H}_2\text{SO}_4$  (swirl and wait 45 s). Reducing agents were then added in the order: 5 ml of 1.5% hydroxylamine hydrochloride; 5 ml of 10% stannous chloride. At this point the solution was ready for analysis using the Coleman Analyzer. Results were reported in parts per billion by weight.

#### Extractable heavy metals

Cadmium, copper, zinc, nickel, chromium and lead were extracted by shaking 10 g of soil with 50 ml of 0.1 N HCl for 1 hour and filtered. The concentrations of extractable heavy metals in solution were determined by atomic absorption spectroscopy as described for total heavy metals.

Extractable Hg was determined by shaking 5 g of soil with 50 ml of 0.1 N HCl for 1 hour. The suspension was filtered, and the soil was leached with an additional amount of 0.1 N HCl until a total filtrate volume of 100 ml was obtained. The mercury in the extract was then determined using the Coleman Mercury Analyzer procedure described above in determining total mercury.

#### Soil Chemistry Data

Tables 4 to 8 contain all available data on the chemical characteristics of the soil from the test cells collected during the period 1973-1978.

Table 4 shows the changes in the free iron oxides, organic carbon, organic-N, pH and conductivity of the soils from the test cells. There is a tendency for a slight decrease of free iron oxides content with wastewater application. Both organic-C and organic-N content increased from 1973 to 1976. Figure 10 shows the organic-C in Test Cells 1 and 6. This is due to application of suspended solids, BOD in the applied wastewater and residue of forage grass. Application of primary effluent is expected to increase both organic-N and organic-C even higher. Figure 11 shows that organic-N is highly correlated with organic-C ( $r= 0.9363$ ). Using this linear regression, it is possible to predict one parameter if the other parameter (organic-C or organic-N) is known. In practice, usually organic-C is easier to analyze for and the precision of analysis is usually higher than that for organic-N. In addition, determination of organic-N requires special apparatus while the analysis for organic-C

may be performed by normal laboratory apparatus (titration, or ignition).

The data in Table 4 show a consistent drop in soil pH from 1974 to 1976. This was explained by Iskandar (1978) as a result of nitrification of applied ammonium-N. Figure 12 illustrates the drop in soil pH of Test Cells 1 and 6 and Figure 13 shows the change in soil pH in the top (0-15 cm) layer from all the test cells. The rise in soil pH after 1976 is a result of applying lime to the test cells (Jenkins et al. 1978).

There is a negligible change in conductivity values with time due to wastewater application to CRREL test cells. This could be due to several reasons including low salt content of applied water, high rainfall and snow fall with more water percolating through the soil than that applied, or low evapotranspiration (ET). Therefore it could be concluded that there is no fear of salt build-up in land treatment soils in the northeastern region of the U.S.A.

Table 5 summarizes the changes in CEC and exchangeable cations during the period 1973 to 1978. As normal for most soils, the surface soils exhibited higher CEC than the underlying layers due to the higher content of organic matter in the surface. There is no apparent trend in long-term changes of CEC and exchangeable cations; however, several conclusions could be drawn from the data. The increase in exchangeable Ca in 1976 data (Fig. 14) is a result of liming discussed previously. Exchangeable Na was <5% of exchangeable cations, indicating that the soils are not likely to become alkaline soils. Exchangeable ammonium was determined in 1977 and 1978 and was found to be very low (<0.2 meq/100 g soil).

Phosphorus is one of the important plant nutrients. Table 6 shows the changes in P concentrations in soils receiving wastewater during the period from 1973 to 1976. Total P determined by ignition is much higher than that determined by the acid extraction method. Because it is easier in some laboratories to determine total acid extractable P than ignition-P, a correlation between the two forms was calculated. The correlation coefficient (*r*) is 0.96 for the samples analyzed in 1973 and 1974 and is 0.99 for those analyzed in 1975, 1976, and 1977. It should be emphasized that a different acid extraction procedure was used in 1975, 1976 and 1977, which may be the reason for the higher values of acid extractable P obtained in those years compared with those obtained in 1973 and 1974.

In land treatment, P is applied in much higher amounts than plant need. Table 6 shows a phosphorus mass balance for test cells 1-6.

In land treatment, P is applied in amounts well above plant requirements. In general, phosphorus uptake by forage grass in land treatment accounts for only 20-30 kg P/ha/yr. Depending on the rate and composition of applied wastewater, more than 100 kg/ha/yr of phosphorus is usually applied. In contrast, we should be more concerned with the fate of unutilized phosphorus. Unpublished data (Iskandar et al.) showed that both Windsor and Charlton soil have a high capacity for phosphorus sorption.

Extractable P (plant available-P) increased by application of wastewater (Table 6). However, no P leaching was observed during the

reported period of study.

Tables 7 and 8 show the changes in total and extractable heavy metals in soils. There is an increase in the concentration of all metals in all test cells. For interpretation of the data up to 1975, the reader should consult Iskandar (1975).

Section II. Climatic Survey at the USACRREL  
Land Treatment Site 1974-1978.

Meteorological Measurements

Explanations of the measured meteorological parameters are presented in Table 9. Meteorological instrumentation, methods and procedures for recording the data were discussed in a previous report (Bilello and Bates 1978).

The U.S. Army Meteorological Team stationed at CRREL is responsible for data collection, calibration of instrumentation, and publication of monthly climatic summaries for the land treatment site. This monthly climatic summary includes hourly measurements, daily tabulation sheets and a monthly summary. Meteorological summary sheets (April 1974-May 1978) for CRREL are presented in Appendix A. Appendix B is the soil temperature during the period Sept. 76 - April 78 for Test Cell 5. Soil temperature for other test cells is available on request.

Climate

The long-term averages for air temperature and precipitation (including snow) for Hanover, N.H., were presented in the previous report (Bilello and Bates 1978).

Tables 10-14 summarize the monthly and yearly averages of the meteorological data obtained. Daily temperature, relative humidity, dew point and wind speed and direction, along with the monthly average of each parameter for April, 1974 to May 1978, are presented in Appendix A.

Air Temperature

A summary of average monthly air temperatures from October 1972 to May 1978 is given in Table 10. The 5-6 year average temperature for the CRREL site is 6.4°C (43.6°F), as compared with the long-term 30-year norm of 7.1°C (44.7°F). The coldest year of the study period at CRREL was 1976, when the temperature averaged nearly 1.1°C (2°F) below normal. The warmest year was 1973, when the temperature was normal, or 7.1°C (44.7°F).

Precipitation

Table 11 summarizes total monthly precipitation from October 1972 to May 1978. Figure 15 is a plot of the monthly total precipitation from April 1974-April 1978. The monthly precipitation amounts (Fig. 15) are not uniform from year to year. Average total precipitation for the 5-6 year period (monthly) is shown on the bar-graph (Figure 16). Total precipitation for CRREL averages 960 mm (37.80 in.), which is 51 mm (2.01 in.) greater than the 30-year (1941-1970) normal of 909 mm (35.78 in.). The total precipitation in 1974 was 123 m (4.86 in.) below normal and in 1976 was 103 mm (4.06 in.) above normal. Figure 16 also illustrates that over the past five years, the peak precipitation generally

occurred during June and October. Therefore, it is recommended that the wastewater application be decreased during those two months. The normal 30-yr monthly precipitation totals for Hanover, N.H. (from "Climatological Data Monthly New England", NOAA) show averages of approximately 76 mm (3 in.)/month; however, Figure 15 and Table 11 demonstrate that precipitation varies considerably on both a monthly and an annual basis.

Tabular record every 4 hours was printed by the CRREL computer staff for each channel daily throughout each month. For example, Appendix B gives the daily soil temperature recorded in °C each month for the center of test cell #1. Records are available in CRREL files on soil temperature data for the other 5 test cells. The uniqueness of this type of plot is that the soil temperature at a known depth can be followed throughout the freeze-thaw, winter and spring seasons.

#### Wind

Table 12 is a summary of average monthly wind speed and direction for the CRREL meteorological site. Wind speeds averaged 1.7 m/sec (3.7 mph) and wind directions were variable, prevailing from the northwest and south. The earlier report (Bilello and Bates 1978) gives an indication of prevailing wind directions, and the latter 4 years of record show little difference from the previous study. The data also confirm the findings "that winter winds are prevailing from the northerly quadrant and summer winds prevail from the southerly quadrant."

#### Solar radiation

Table 13 shows solar radiation in langleyes ( $\text{g-cal}/\text{cm}^2$ ) per day reported as monthly averages. Yearly averages are also shown for 1974-1977. Maximum amounts occurred in July (approximately 500 langleyes/day) and minimum amounts (approximately 100 langleyes/day) in December.

#### Evaporation

Table 14 shows the evaporation data at the CRREL test cells. At this site evaporation is only significant during the period of May to October. Maximum evaporation occurs in May, June, and July, with the highest total of 164 mm recorded in May 1975.

#### Soil temperature

Soil temperature data presented in Appendix B cover the period September 1976-April 1978. These data were recorded by a Kaye Data Logger programmed to record and store on paper tape thermocouple outputs every 4 hours at 0-24-in. soil depths throughout the 6 test cells. A tabular record every 4 hours was printed by the CRREL computer staff for each channel daily throughout each month. For example, Appendix B gives the daily soil temperature recorded in °C each month for the center of test cell #1. Records are available in CRREL files on soil temperature data for the other 5 test cells. The uniqueness of this type of plot is that soil temperature at a known depth can be followed throughout the freeze-thaw, winter and spring seasons.

Table 9. Explanation of meteorological parameters

<u>Parameter</u>	<u>Explanation</u>
Station Pressure	Atmospheric pressure taken hourly.
Precipitation	Amount of liquid precipitation, hourly total.
Dry bulb Temperature	Ambient temperature, taken hourly.
Relative Humidity	Relative humidity, taken hourly.
Snow depth*	Amount of snow accumulation
Wind speed Wind direction	Wind speed and direction measured at 4 m above surface evaluated for an hourly average, peak gusts with time and direction on a daily and monthly basis, and a prevailing wind direction for the day.
Vertical Eppley	Total incoming solar radiation falling on a horizontal plane. Evaluated for an hourly average.
Inverted Eppley radiation	Reflected incoming solar radiation falling on a horizontal plane. Evaluated for an hourly average.
Evaporation	Total amount daily measurements made with an X-3 pan.

\* Snow Depth is measured by the observer when site is visited.

ALL METEOROLOGICAL PARAMETERS ARE TABULATED ON THE 24-HOUR CLOCK,  
LOCAL STANDARD TIME

TABLE 10

Air Temperature ( $^{\circ}$ F)\* October 1972 to May 1978

MONTH	1972	1973	1974	1975	1976	1977	1978	Average Temp. ( $^{\circ}$ F)
January		21	20	21	10	9	16	16.2
February		17	18	21	26	10	12	19.0
March		38	30	28	32	36	27	31.8
April		44	45	38	48	43	39	42.8
